Background  The number of patients infected by HIV and hepatitis has increased over the years. Some of them have swallowing difficulties that require the placement of nasogastric or gastrostomy tubes. These chronic treatments need high compliance rates to avoid antiviral drug resistance and, eventually, treatment failure.

Purpose  To review the existing antiviral drugs literature and develop administration recommendations for patients with swallowing problems.

Materials and Methods  Formulations and recommendations were obtained directly from the manufacturers, or by a PubMed search and a search on the Micromedex database, when information was not available. A guide published by SENPE with physicochemical and formulation properties of drugs was also checked.

Results  Table 1 shows the results. Extensive administration recommendations were found during literature searches but are not included in the present abstract. There was no information about the administration of adeeforv, maraviror or saquinavir through gastrostomy or nasogastric tube.

Conclusions  Treatment compliance is key to ensuring the success of chronic antiviral treatments and it is important to consider special situations, such as swallowing problems. This guide for nasogastric or enteral administration helps clinicians to choose the most appropriate treatment. Further research is needed to determine specific bioavailability data.

Abstract DGI-024  Table 1  Antiviral Drug Formulations and Administration

DGI-025 DEVELOPMENT OF A PROTOCOL FOR THE TREATMENT OF VITAMIN D DEFICIENCY/INSUFFICIENCY IN ADULTS

doi:10.1136/ejhpharm-2013-000276.291

1 M Kieran, D O’Sullivan, J Brady, S McQuaid, C Meegan. Mater Misericordiae University Hospital, Pharmacy Department, Dublin, Ireland (Rep.); 2 Mater Misericordiae University Hospital, Biochemistry Department, Dublin, Ireland (Rep.); 3 Mater Misericordiae University Hospital, Department of Endocrinology, Dublin, Ireland (Rep.)

Background  Recent medical research has highlighted that vitamin D deficiency/insufficiency is a significant public health problem. A UK study found that more than 50% of the adult population had insufficiency and 16% had deficiency. [1] Low vitamin D levels have been linked to rickets, malignancies, cardiovascular disease, type 2 diabetes and some autoimmune diseases. [1] Therefore, appropriate management of Vitamin D deficiency/insufficiency is essential.

This increased awareness among prescribers of treating vitamin D deficiency was apparent in the Mater Misericordiae University Hospital (MMUH):

- Medicines Information enquiries regarding treatment of vitamin D deficiency had increased.
- Biochemistry assay numbers for vitamin D (25-hydroxy-vitamin D) had increased.
- Requests to the endocrinology service for guidance on the treatment of vitamin D deficiency had increased.

MMUH clinicians were experiencing difficulty treating patients with vitamin D deficiency/insufficiency as:

- There were no definitive guidelines for the treatment of vitamin D deficiency/insufficiency.
- There is no licenced preparation containing cholecalciferol or ergocalciferol as a single drug formulation in Ireland.

Guidance for MMUH clinicians was therefore necessary.

Purpose  To develop a protocol for the treatment of vitamin D deficiency/insufficiency.

Materials and Methods  Review of treatment algorithms for treatment of vitamin D deficiency/insufficiency in the literature.

Compilation of vitamin D products currently available in Ireland. Liaison with MMUH clinical staff to ensure production of a protocol that is applicable to all disciplines.

Results  A treatment algorithm was prepared detailing two specific guidelines for the treatment of:

- Vitamin D deficiency (serum 25-hydroxy-vitamin D <25 nmol/L)
- Vitamin D insufficiency (serum 25-hydroxy-vitamin D 25–50 nmol/L)

The protocol recommends vitamin D preparations, including one unlicensed preparation, which are available in the MMUH and accessible in the community.

The protocol also recognises the limitation of giving guidance on treating a condition that may be affected by numerous clinical scenarios or that may require input from specialist physicians. Where applicable, consultation with the relevant medical team(s) is recommended.

Conclusions  MMUH patients diagnosed with vitamin D deficiency/insufficiency are treated in a standardised manner in accordance with available clinical evidence. The protocol ensures delays in treatment are minimised and physicians are aware of the particular considerations involved in the management of vitamin D deficiency/insufficiency.

DGI-026 DRUG USE IN PATIENTS WITH METASTATIC BREAST CANCER

doi:10.1136/ejhpharm-2013-000276.292

A Madrid Paredes, R López Sepúlveda, E Puerta García, N Martínez Casanova, B Cancela Díez, MA Calleja Hernández. Virgen de las Nieves University Hospital, Pharmacy, Granada, Spain

Background  The historic poor prognosis and survival of metastatic breast cancer (MBC) patients has been improved in the last decades by the introduction of multimodal treatment.

Purpose  To analyse the MBC population and describe the prescription profile used.
Materials and Methods We conducted a retrospective observational study. We included all patients with MBC in 2007. Using the digital history, sociodemographic variables (age, sex), clinical (histologic type, oestrogen receptor, ER, progesterone receptor, PR, human epidermal growth factor receptor 2, HER-2, progression from primary tumour, appearance and location of metastases, lymph node involvement, survival, deceased) and therapeutic histories (radiotherapy, hormone therapy, chemotherapy) were collected.

Results We included 43 patients with a mean age of 54.5 years (100% female). The most common histological types were infiltrating ductal (60%) and lobular (24.4%) tumours. ER and PR were positive in 75.6% and 50%, respectively. Overexpression of HER-2 was negative in 73.7%. 69.2% of patients with MBC had progressed from primary tumour. The metastatization appeared at an average of 44.1 months since diagnosis. The most common sites of metastases were bone (34.6%), lung (16.4%) and liver (20.8%).

93.9% of patients had lymph node involvement and 77.6% were in the terminal phase. 93.5% of patients had received radiotherapy. Endocrine therapy used was fulvestrant (22.9%), anastrozole (21.6%), tamoxifen (20.2%). All patients received chemotherapy, the most used first-line schemes being: epirubicin/cyclophosphamide/docetaxel (50.6%), cyclophosphamide/epirubicin/fluorouracil (20.4%) and cyclophosphamide/methotrexate/fluorouracil (16.6%) in combination with trastuzumab or not. In successive lines, combinations of vinorelbine, docetaxel, capecitabine, carboplatin, gemcitabine were prescribed. Lapatinib and bevacizumab were used from the fourth-line treatment.

Conclusions Radiotherapy, not indicated in MBC, was used in early stages of the disease. Due to the variability of patients, treatment regimens are diverse and a predefined schema is not appropriate. Bevacizumab and lapatinib were used in late-stage treatment in patients who had not responded to standard treatment.

DGI-027 EFFECTIVENESS AND SAFETY OF CLOFARABINE IN PAEDIATIC PATIENTS WITH ACUTE LEUKAEMIA

doi:10.1136/ehjpharm-2013-000276.293

MC Garas-Martín de Almagro, S De la Fuente Ruiz, N García Melero, B Galvez Criado, T Brieva Herrera. Hospital Universitario Reina Sofia, Pharmacy, Cordoba, Spain

Background Clofarabine is a purine nucleoside antimetabolite, a second-generation antineoplastic indicated for the treatment of acute lymphoblastic leukaemia in paediatric patients (≤ 21 years) who have relapsed or are refractory after receiving at least two prior regimens and who have no other treatment options that provide a durable response.

Despite progress in leukaemia treatment, most children who relapse have a dismal prognosis. New approaches are needed.

Purpose To assess the effectiveness and safety of clofarabine in paediatric patients with refractory or relapsed acute leukaemia.

Materials and Methods This was an observational retrospective study. We included all paediatric patients diagnosed with acute leukaemia who received clofarabine as antineoplastic treatment during 2007–2011.

We used the computer programme Oncosafe for prescribing, preparation and validation of chemotherapy treatments and collected data for number of patients, age, sex, weight, height and treatment schemes lines administered prior to clofarabine.

In addition, we used medical records as a source of safety data regarding potential adverse reactions due to clofarabine.

Results During the study period clofarabine was administered to a total of six paediatric patients (4 boys and 2 girls) with a median age of 11.5 years (5–16 years).

They had received a median of 2 prior lines of treatment. Later treatment schedules used in 83.3% of these patients included 40 mg/m² clofarabine in combination with other chemotherapy drugs with a median of 2 administered cycles. In the rest (1/6) clofarabine was used at 52 mg/m² as monotherapy.

66.6% of patients achieved complete remission and 50% were transplanted.

Mucositis grade IV and pancytopenia were detected in two patients and palmar erythema in one patient. All patients had a transient transaminase increase.

No conflict of interest.

DGI-028 EFFECTIVENESS AND SAFETY OF RITUXIMAB IN IDIOPATHIC THROMBOCYTOPENIC PURPURA

doi:10.1136/ehjpharm-2013-000276.294

JJ Elizondo, G Elizondo, M Noceda, E Pellejero, M Elviro, M Gutierrez. CHN Navarre Health Service, Pharmacy B, Pamplona, Spain; CHN Navarre Health Service, Health Department, Pamplona, Spain

Background Idiopathic thrombocytopenic purpura (ITP) is an autoimmune disorder characterised by low platelet count and may be responsible for episodes of mucocutaneous bleeding of varying severity.

Purpose The study evaluates the effectiveness and safety of rituximab in patients who have not responded to first-line treatment.

Materials and Methods We performed a retrospective observational study, between 2009–2011, in adult patients who had not responded to first-line treatment (high-dose corticosteroids or non-specific IV immunoglobulins), or who were intolerant to such alternatives. Both splenectomised and non-splenectomised patients were included. The dose employed was 375 mg/m² q7d for four weeks. We considered it a partial response if the platelet count exceeded 50 × 109 cells/L, and a complete response if the count was greater than 100 × 109 cells/L. Previous duration of thrombocytopenia, platelet counts before treatment and after 4 weeks, percentage of patients having a satisfactory response, median time to response, duration, occurrence of petechiae and mucocutaneous bleeding and tolerability of the infusion were examined.

Results We recruited 22 patients, 12 men and 10 women. The mean age of the sample was 55.6 years (range: 19–88) and a previous mean duration of ITP of 7.5 years (range 0.35 to 41). The mean platelet count before treatment was 32.8 × 109 cells/L (range: 6–70), and increased to 120×109 cells/L (range: 23–591) after completion within four weeks.

10 patients (45.5%) experienced a complete response and in 8 patients (36.3%) the response was partial, while 4 (18.2%) patients experienced no response. The mean time to get some response was 2.3 weeks (range 1–4 weeks), and it continued a median of 10.5 months (range: 1–25). Among patients who had some response, in 2 cases petechiae and bleeding were detected again, while in 3 the platelet count fell below 50×10⁹ cells/L. The other 13 patients who responded continue today with a platelet count within the target range and without clinical symptoms. The infusion was well tolerated in all cases.

Conclusions Rituximab seems an effective and well-tolerated alternative in patients with refractory ITP who require chronic treatment. This study and literature show that more than 50% of patients respond to treatment, and it may be an alternative to splenectomy. However, further prospective studies are required to define the optimal position of rituximab in the treatment of ITP.
