gave it to a nurse or doctor on the ward. The nurse and doctor would consider the suggested solution and tick off either ‘Yes I agree and have prescribed a laxative’ or ‘No I don’t agree’ and return the handout to the pharmacist.

**Results**

A total of 2282 patient medicines were screened and 681 patients had been prescribed opioids. 236 of the patients receiving opioids did not have a prescription for a laxative and the pharmacist filled in an intervention handout for these patients. 25 interventions were accepted by the doctors on the wards and laxatives were prescribed. Unfortunately about 50% of the handouts were not filled in an intervention handout for these patients. 25 interventions were accepted by the doctors on the wards and laxatives were prescribed. Unfortunately about 50% of the handouts were never returned to the pharmacy, making it difficult to determine the exact number of interventions accepted. Also a number of patients were discharged before action could be taken. If the intervention were to be repeated the following would be relevant to improve the outcomes of such a campaign. It is important to consider the selection of wards to include in the campaign. On wards where the patients are discharged after a few days it can be difficult to implement the interventions under time pressure.

**CPC-117 PROSPECTIVE REGISTRY FOR EVALUATING THE EFFECTIVENESS OF BEVACIZUMAB ALONE OR WITH IRINOTECAN IN RECURRENT GLIOBLASTOMA**

doi:10.1136/ehjpharm-2013-000276.574

1M Viani, iM Cucci, iS Colombini, iE Agostino, iF Attanasio, iM Cerotti, iR Banfi. Careggi Hospital, Pharmacy Department, Florence, Italy; iISPO, Molecular and Nutritional Epidemiology Unit, Florence, Italy

**Background**

Recurrent glioblastoma is nearly always fatal, with median survival rates of approximately 12–14 months. Previous phase II clinical trials showed promising results with bevacizumab, alone or in combination with irinotecan, in patients with recurrent glioblastoma.

**Purpose**

To assess whether the survival of patients with recurrent glioblastoma receiving bevacizumab alone or with irinotecan in everyday practise is comparable to that reported in clinical trials.

**Materials and Methods**

This was a retrospective observational study conducted at a single hospital in Italy. Patients with recurrent glioblastoma who had received bevacizumab alone or with irinotecan from January 2009 to September 2011 were included in our study.

The main outcome measures were progression-free survival (PFS), overall survival (OS), and rates of PFS and OS at 6 months.

**Results**

Median PFS was 5.1 months in the bevacizumab group \( (n=9) \) and 15.4 months in the bevacizumab + irinotecan group \( (n=10) \), with 6-month PFS rates of 45% and 69%, respectively. Median OS was 6.8 months for bevacizumab alone and 11.1 months for bevacizumab + irinotecan, with 6-month OS rates of 100% and 90%, respectively.

**Conclusions**

Although the number of patients included is not sufficient to allow a conclusive statement about the place of bevacizumab in the treatment of recurrent glioblastoma, the data appear promising, and are consistent with the results of clinical trials.

No conflict of interest.

**CPC-118 QUICK WINS – INNOVATIVE AND ECONOMIC FOCUS ON USE OF MEDICINES**

doi:10.1136/ehjpharm-2013-000276.575

1A Kobber Jensen, iO Vistrup Tomsen, iB Ørskov Lindhardt. iRegion Hovedstadens Apotek, Clinical Pharmacy Services, Hillerød, Denmark; iHillerød Hospital, Lung- and Infection, Hillerød, Denmark

**Background**

Medicines account for a large part of the budget in Danish hospitals. National and regional actions are initiated to control drug expenses. Local initiatives aim at involving doctors, nurses and pharmacy staff in taking everyday responsibility for the rational use of drugs.

**Purpose**

To establish systematic and documented cooperation between the Local Drug and Therapeutics Committee, the clinical staff and the pharmacy staff to systematically identify and intervene on avoidable medicines expenses.

**Materials and Methods**

10 focus areas were identified: Handling free-of-charge drugs, systematic feedback from top-up-service, the staff’s (unofficial) use of medicines, reanalysis of statistical material on drug use, input from other pharmacy departments, analysing the use of the 120 most expensive drugs, analysis of disposed medicines, emptying vials (expensive drugs), shift from IV to oral antibiotics, and use of the patients’ own medicine, when possible. Through a systematic approach and co-operation on all levels of the organisation, the 10 focus areas were implemented in everyday practise at the hospital.

**Results**

The results were recorded in a report to the Local Drug and Therapeutics Committee in January 2012. A financial estimate was made for 4 out of 10 focus areas. The total result for the 4 intervention areas amounts to a saving of DKK 1,154,500 (€155,00/year). The saving is based on a conservative estimate. For the remaining six focus areas interventions are still taking place. In 2012 the initiative is spreading to other hospitals in the Capital Region.

**Conclusions**

Through systematic and well-documented cooperation between the Local Drug and Therapeutics Committee, the clinical staff and the pharmacy, it has proved possible to save a considerable amount on the total hospital budget.

**CPC-119 RANDOMIZED CONTROLLED TRIAL OF CLINICAL PHARMACY MANAGEMENT OF PATIENTS WITH TYPE 2 DIABETES IN AN OUTPATIENT DIABETES CLINIC IN JORDAN**

doi:10.1136/ehjpharm-2013-000276.576

1A Jarab, iS Alqudah, iT Mukattash, iG Shattat, iA Al-Qirim. iAlzaytoonah University of Jordan, Pharmacy, Amman, Jordan; iJordanian Royal Medical Services, Pharmacy, Amman, Jordan; iJordan University of Science and Technology, Pharmacy, Irbid, Jordan

**Background**

Glycaemic goals are often not achieved in patients with type 2 diabetes despite the availability of many effective treatments and the documented benefits of glycaemic control in the reduction of long-term microvascular and macrovascular complications.

**Purpose**

To evaluate, in a randomised, controlled trial, the impact of a clinical pharmacy service on clinical outcomes in patients with type 2 diabetes.

**Materials and Methods**

A total of 171 patients (85 interventions vs. 86 usual care) participated in the study. Intervention patients had individualised education and treatment recommendations from a clinical pharmacist while control patients received usual care provided by the clinic. The primary outcome measure was glycaemic control manifested by HbA1c reductions. All other data collected including systolic and diastolic blood pressure, total cholesterol, low-density lipoprotein (LDL), high density lipoprotein (HDL), serum triglycerides, medication adherence, and necessary self-care activities formed secondary outcome measures. Between-group differences in the amounts of change from baseline to 6-month follow-up were tested and a p value of <0.05 was considered statistically significant.

**Results**

Compared with baseline values, patients in the intervention group had a mean reduction of 0.8% in HbA1c versus a mean
RANITIDINE-INDUCED SYSTEMIC HYPERSENSITIVITY REACTION: A CASE REPORT

doi:10.1136/ehjpharm-2013-000276.577

M Geneste, S Bourget, P Brun, I Dufrene, H Hida. Hospital, Pharmacy, Valence Cedex 08, France; Hospital, Pneumology, Valence Cedex 08, France

Background Ranitidine is a histamine-2-receptor antagonist (antiH2) widely used with an excellent safety record. It’s a drug included in the premedication for several chemotherapy regimens.

Purpose To report a case of hypersensitivity to ranitidine.

Materials and Methods Case report, literature review.

Results A 68-year-old man was being followed at hospital for management of metastatic lung carcinoma. A third-line treatment with weekly paclitaxel had been decided. The usual premedication includes intravenous ondansetron, ranitidine, dexchlorpheniramine and methylprednisolone. The patient’s anamnesis hadn’t reported any allergic events.

During the first course, the patient presented pruritus 5 minutes after ondansetron and ranitidine injections. Hypotension and warmth occurred despite the administration of dexchlorpheniramine. 120 mg of methylprednisolone resolved the hypersensitivity completely before the patient received paclitaxel, without further event.

During the next course, ondansetron was replaced by metoclopramide. During the ranitidine infusion the patient presented sweats, hypotension and bronchospasm. Ranitidine infusion was stopped and methylprednisolone overcame the reaction. The patient’s condition allowed paclitaxel administration although he refused dexchlorpheniramine.

The need for antiH2 and the most appropriate premedication for the next courses were discussed by the clinician and pharmacist. Hypersensitivity reactions are reported in ranitidine’s SPC with an estimated rare frequency and also in the literature review. A case also reported a cross-reaction between antiH2 and other antihistamines [1], while another author excluded it [2].

As no allergic investigation has been performed, all antihistamines have been removed as a precaution. For subsequent courses the premedication included metoclopramide 10 mg and methylprednisolone 80 mg. No other incidents have been reported. This search didn’t formally establish the need for antiH2 in paclitaxel premedication.

Conclusion: This case has been reported to the pharmacovigilance centre and reminds clinicians that even commonly used and generally well-tolerated substances can cause serious side effects.

RISK FACTORS IN THE INCIDENCE OF CHEMOTHERAPY-INDUCED EMESIS

doi:10.1136/ehjpharm-2013-000276.579

S Félix Caballero, MJ Gándara Ladrones De Guevara, JF López Vallejo, MA Blanco Castaño, C Palomo Palomo, CM Martinez Diaz. Puerto Real University Hospital, Pharmacy Department, Puerto Real, Spain

Background Chemotherapy-induced nausea and vomiting (CINV) are the most common side effects after the administration of anti-cancer drugs. CINV appears in a variable percentage of patients, depending on the cytostatic agent and patients’ risk factors.

Purpose The aim of this study was to evaluate the effect of the risk factors on the incidence of emesis after the administration of the first cycle of chemotherapy.

Materials and Methods A literature search was conducted for articles addressing the risk factors in CINV. Younger age, female sex, history of motion sickness or pregnancy-induced vomiting, radiotherapy and anxiety/depression were included. A history of alcohol intake was considered a protective factor and it was graded as none, mild (1–5 drinks/month), moderate (6–14) or high (>14) consumption. The impact on complete response (CR) of those risk factors for
