Purpose

in the TPN facility, it was decided to produce calcium gluconate in plastic or glass ampoules. The estimated consumption was around 10 mL to import an alternative source but the administrative delay was too long. The only sources available within a month were 10 mL packages of the calcium source (10% sterile solution of calcium gluconate in water) for Parenteral Nutrition (TPN). In June 2012, a shortage of sterile calcium gluconate bags has ensured the continued production of TPN.

Conclusions

The T otal Parenteral Nutrition (TPN) production facility of our children’s hospital produces around 20,000 units per year with 2 Baxa EM2400 compounders. In June 2012, a shortage of the calcium source (10% sterile solution of calcium gluconate in water) for Parenteral Nutrition (TPN). In June 2012, a shortage of sterile calcium gluconate bags has ensured the continued production of TPN.

Results

The failure modes that show higher benefits in risk mitigation are the wrong drug and wrong dosage with a PRI decrease of 80% (from 50 to 10). Indeed the redundant controls (vision system, scale, photocontrols) on the loaded vials guarantee the compounding of the right drug. In addition, the drug is dosed with a calibrated syringe pump and independently verified with the scale. The other failure modes reported a risk reduction of 50% and on the whole the total PRI passes from 186 in case of the manual activity to 63 for the robotic one.

Conclusions

The FMECA analysis shows an overall reduction of the PRIs of over 66% with the robotic compounding with respect to the manual production. Automation not only decreases the occurrence of dangerous events thanks to the complete control of every single step of the compounding process, but also develops an error detection system through independent verification processes.

Shortage of Sterile Calcium Gluconate Stock Solution for Parenteral Nutrition: What is the Alternative and How Much Does it Cost?

V. Siorat, S Serrano, P Jorret, P Vaconsin, F Briot, T Storne, M Perrinet.

Background

The Total Parenteral Nutrition (TPN) production facility of our children’s hospital produces around 20,000 units per year with 2 Baxa EM2400 compounders. In June 2012, a shortage of the calcium source (10% sterile solution of calcium gluconate in 500 mL bottles) occurred. To overcome this problem, we first tried to import an alternative source but the administrative delay was too long. The only sources available within a month were 10 mL plastic or glass ampoules. The estimated consumption was around 300 ampoules per production day. To maintain efficiency and safety in the TPN facility, it was decided to produce calcium gluconate bags from 10 mL ampoules by sterilising filtration to maintain the safety of preparation.

Purpose

To evaluate the additional cost incurred by setting up this preparation and the increased time required.

Materials and Methods

The pharmacy prepared calcium gluconate bags (250 mL) from plastic ampoules after filtration (0.22 µm filters (Sterivex Millipore), using a Repeater Pump (Baxter), in a laminar air flow cabinet. The cost of setting up a new procedure and of the compounding was evaluated in different categories (materials, checking, staff).

Results

228 bags were produced during the 20 days on which we could not obtain the 500 mL bottles (19 batches of 12 bags).

The cost of one 250 mL compounded bag was €44.23 (materials: €20.22, staff: €14). In addition, developing the system cost €4,287.72. The overall additional cost was therefore €155.22/L.

Conclusions

Despite a major additional cost, compounding calcium gluconate bags has ensured the continued production of TPN. From a risk assessment point of view, identification of several suppliers and increasing our stocks of the raw materials would make out-of-stock situations easier to manage in future.

Stability of Frozen Ceftazidime Solution in Polypropylene Syringes for Intravitreal Injection

J Vigneron, A Daul, N Sobalak, H Zenier, I May, B Demoré. Centre Hospitalier Universitaire de Brabois, Pharmacy, Vandoeuvre, France

Background

Ceftazidime is used for the treatment of endophthalmitis by intravitreal injection. For this emergency treatment, the syringes must be available immediately in the pharmacy. The stability at 2–8°C is limited and does not allow batch production.

Purpose

To study the stability of ready-to-use ceftazidime solution at 20 mg/mL in 0.9% sodium chloride in polypropylene syringes after storage at −20°C, to allow preparation in advance.

Materials and Methods

The analytical conditions were: Column C18 5 µm 200 × 4.6 mm. Mobile phase (ammonium acetate buffer 0.1 M pH 7.5/acetonitrile 20/80%), flow rate: 1 mL/min, wavelength: 256 nm.

The HPLC method was validated according to ICH guidelines (linearity, repeatability, stability-indicating capability).

Syringes were stored at −20°C and 4°C to compare with the literature data.

Results

Stability was defined according to ICH guideline Q1A: above 95% of the initial concentration of ceftazidime and concentration of degradation products less than 2%. After storage at 4°C, the ceftazidime concentration fell under 90% after 3 weeks and there was 65% of the initial concentration after 90 days.

The ceftazidime solution at 20 mg/mL was stable for 3 months at −20°C with more than 96% of the initial concentration and degradation products less than 2%. After storage at 0°C, the ceftazidime concentration fell under 90% after 3 weeks and there was 65% of the initial concentration after 90 days.

Conclusions

Ceftazidime 20 mg/mL in 0.9% sodium chloride was stable for 3 months at −20°C. This allows batch preparation in advance and the immediate availability of the syringes to treat patients.

Six Sigma in Healthcare: An Application in the Monitoring of Albumin

F Ciro, P Marrone, R Citati, ‘ARNAS Civic Hospital, Pharmacy Operative Unit, Palermo, Italy; 4University of Palermo, Engineering department, Palermo, Italy

Background

The high off-label use of albumin persuaded the pharmacy to introduce a request form that uses the internationals guidelines to assess whether the use of albumin is appropriate. This has resulted in a clear reduction in the costs.

Purpose

To monitor the wards using six sigma methodology (a statistical concept that measures a process in terms of defects); to ensure that all procedures have been followed correctly.

Materials and Methods

696 forms for albumin prescriptions coming from 26 wards (August to December 2011) were analysed using Minitab software, which checks the frequency of the best correct requests (type 1), partially correct requests (type 2) and incorrect requests (type 3). For each ward the β coefficient was used to connect the relationship between the ward and their requests. The wards were grouped into 4 ranges on confidence intervals for the odds ratio (OR) of a width equal to 0.3 called A,B,C,D and then a final logistic regression analysis was made.

Results

The analysis showed that group A was the most efficient in terms of probability of obtaining better results, followed by groups D (OR 0.36), C (OR 0.19) and B (OR 0.09). The total number of requests received was: 43% type 1 (299/696); 26% type 2 (181/696); 31% type 3 (216/696). Group B showed the worst result with 51% type 3 requests (58% of the total requests for type 3). Using six sigma we have achieved a cost saving of about €15,000.

Conclusions

The results encourage us to apply this methodology to other fields.
