Background The intravenous administration of antibiotics remains the route of choice at patient admission. Although the early-oral switch once the clinical stability has been achieved, has demonstrated to be effective and safe in other settings, its implementation in the pneumology ward has not been studied.

Purpose To assess the effectiveness and safety of an early-oral antimicrobial switch protocol in the pneumology ward.

Material and methods Quasi-experimental study performed in a 400-bed tertiary hospital. The protocol was implemented in March 2018 and therefore two groups were identified: intervention group (March to August 2018) and control group (March to August 2017). All patients admitted to the pneumology ward were treated with intravenous antibiotics that, in turn, were available orally: therefore, amoxicillin/clavulanate, fluoroquinolones, trimethoprim-sulfamethoxazole, clindamycin, and azithromycin were included.

Results A total of 200 patients were included. Main clinical outcomes are summarised in table 1.

Conclusion The implementation of an early-oral antimicrobial switch protocol in the pneumology ward is effective and safe.

</tbody>
</table>

The early-oral antibiotic switch could decrease the days of catheterisation and the potential related adverse outcomes, with a shortening in the length of stay.
these recommendations will help to avoid antibiotic-resistance and side effects in patients.

4CPS-069 IMPACT OF IMPLEMENTING A GLOBAL COLLABORATIVE PHYSICIAN-PHARMACIST STRATEGY ON PROPHYLACTIC ANTIBIOTIC PRACTICES IN A UNIVERSITY HOSPITAL CENTRE

Background Among different approaches to prevent surgical site infections, antibiotic prophylaxis is substantially important. According to previous published papers, surgical antibiotic prophylaxis (SAP) practices could be optimised by the implementation of isolated strategies.

Purpose
• To identify risk factors associated with non-compliance towards prophylactic antibiotic guidelines.
• To test the impact of a combined intervention strategy on compliance towards prophylactic antibiotic guidelines.

Material and methods A quasi-experimental study with a pre-test–post-test evaluation was carried out on five types of intervention: hip prosthesis, coronary artery bypass grafting, colorectal surgery, transurethral resection of the prostate and endoscopic retrograde cholangiopancreatography. Compliance with guidelines was evaluated in 11 criteria within the pre-test and intervention groups.

• In order to identify risk factors associated with non-compliance, a retrospective observational transversal study was carried out in the pre-test group using a multivariate statistical analysis (Wald test). Odds ratios for the relationships between each independent variable and the outcome variable were then determined.
• We tested a combined intervention strategy that included: the pre-operative delivery of nominative kits containing the antibiotics with a recommendation paper adapted to patient factors; a pharmacist participating in antibiotic stewardship team for compilation of guidelines and their distribution for implementation; audits; feedback; educational seminar and outreach visits; and the development of an internal computer-based decision tool. For comparison between the two groups (pre-test and intervention groups), data were analysed using $\chi^2$ and t tests for, respectively, categorical and continuous data.

Results The pre-test group (11 January 2016 – 22 April 2016) and the intervention group (9 January 2017 – 21 April 2017) included, respectively, 130 and 118 interventions.

• The multivariate statistical analysis showed, as in previous studies, that true penicillin allergy, certain types of surgery and some practitioners were associated with non-compliance within the pre-test group.

4CPS-070 DOES ANTIBIOTIC CONSUMPTION PREDICT THE INCIDENCE DENSITY OF HEALTHCARE-ASSOCIATED INFECTIONS?

1A Peric*, 2S Vezmar Kovačević, 8M Milenković, 4V Suljačić. 1Military Medical Academy – Faculty of Medicine, Sector of Pharmacy, Belgrade, Serbia; 2Faculty of Pharmacy- University of Belgrade, Department of Pharmacokinetics and Clinical Pharmacy, Belgrade, Serbia; 3Military Medical Academy, Sector of Pharmacy, Belgrade, Serbia; 4Military Medical Academy- Medical Faculty, Department of Healthcare-Related Infection Control, Belgrade, Serbia

10.1136/ejhpharm-2019-eahpconf.219

Background The decrease in healthcare associated infections (HAI) in intensive care units (ICUs), related to surgical-site infections (SSIs) and Clostridium difficile infections (CDIs), as well as antibiotic consumption, are the main goals in the hospital setting.

Purpose The aim of this study was to evaluate the antibiotic consumption, and to relate it with HAI incidence density (ID) and incidence rate (IR).

Material and methods The study was conducted from 2011 to 2016 in a tertiary hospital. Through regular hospital surveillance, we identified all patients with a new HAI. Data on the use of antibacterials for systemic use were expressed as defined daily dose per 100 bed days (DDD/100 BD).

Results The highest ID of HAI was observed in patients in surgical ICUs (25.5–47.2/1000 patient days), while the IR of SSIS was 3.76%. Moreover, the highest ID of CDI in medical patients was 6.2, while in surgical patients it was 4.3 per 10 000 patient days, while, at the same time, the antibiotic consumption was the lowest (31.2 DDD/100 BD). The most frequently used antibiotics, on average, were cefalosporins, aminoglycosides and carbapenems (16.0±2.3, 4.8±0.7, 4.3±0.7 DDD/100 BD, respectively). The decrease in use of glycopeptides and fluorochinolones was predictive of higher ID of medical CDIs (p<0.03).

Conclusion The most frequently used antibiotics were not associated with HAI. However, the decrease in use of glycopeptides and fluorochinolones was associated with higher ID of CDIs. Simply decreasing the consumption of antibiotics with high risk for HAI may not be sufficient.
